

Fixed-Window 2-Gap Cohort: Real Excess vs Random Benchmark

Observed boundary effect (zoomed)

cohort endpoint

- Q=17
- Q=101
- Q=251
- Q=503

reference scales

- zero
- head scale ($c=1/2$)
- square-window scale ($c=1$)

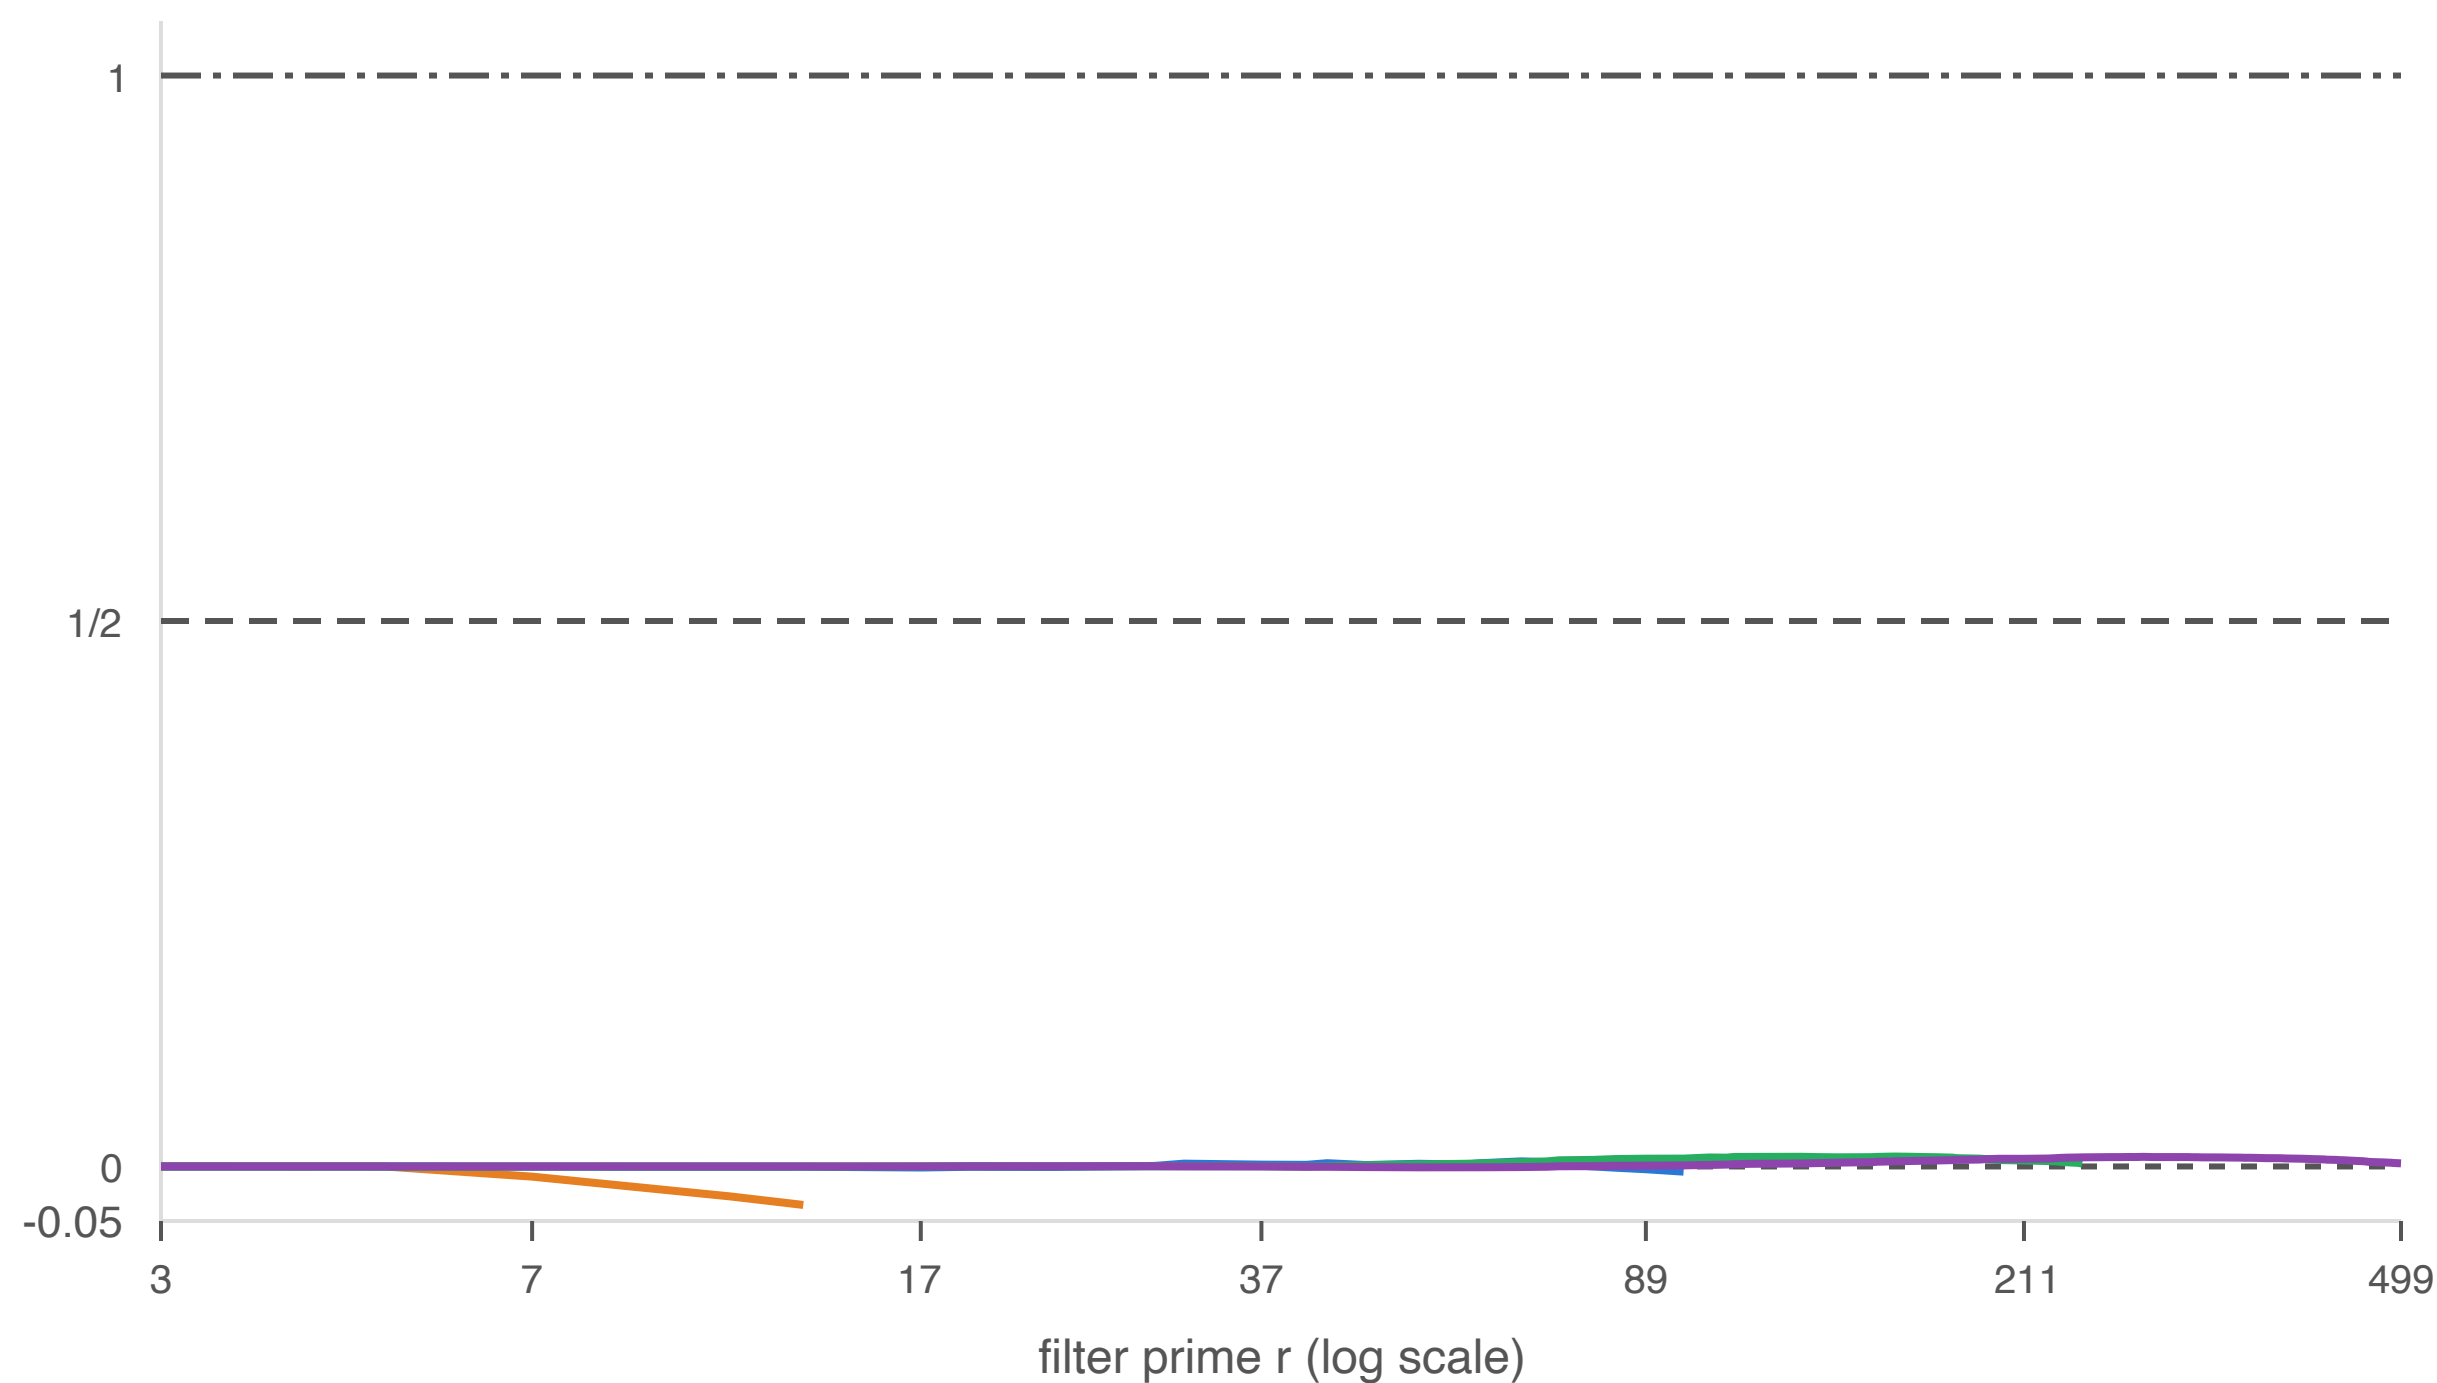

Top: measured real-minus-random cumulative log-hazard excess.

Bottom: the same excess normalized as $c_{\text{eff}} = \text{excess} / (2 \log r)$.

The $c=1/2$ and $c=1$ lines are comparison scales, not fitted claims.

Negative values mean less destruction than the independent-random benchmark.

Distance from comparison scales (normalized)

Cumulative log-hazard excess over the independent-random benchmark $2/r$ at each incoming filter r
